# Installing on macOS

Install Anaconda Distribution using either the install wizard or the command line instructions below. If you are unsure, choose the graphical install (wizard).

## Wizard install

More of a visual learner? Watch the Installing Anaconda (Mac) video in the course linked below!

Download Link: https://learning.anaconda.cloud/get-started-with-anaconda/18200?utm_campaign=learning&utm_medium=documentation&utm_source=anacondadocs&utm_content=installmac

1. Download the graphical macOS installer for your version of Python.

2. Double-click the downloaded file and click Continue to start the installation.

3. Answer the prompts on the Introduction, Read Me, and License screens.

4. Anaconda recommends that you choose Install for me only. If you do not want to install Anaconda Distribution into your home folder, select Install on a specific disk….

*Caution: The installer may skip the Destination Select page during installation, which will cause the installation to fail. If the installer skips this page, click Change Install Location… on the Installation Type page to get to this step.*

Note:

If you get the error message "You cannot install Anaconda in this location," reselect Install for me only.

5. Click Install.

6. Once the install is complete, click Continue.

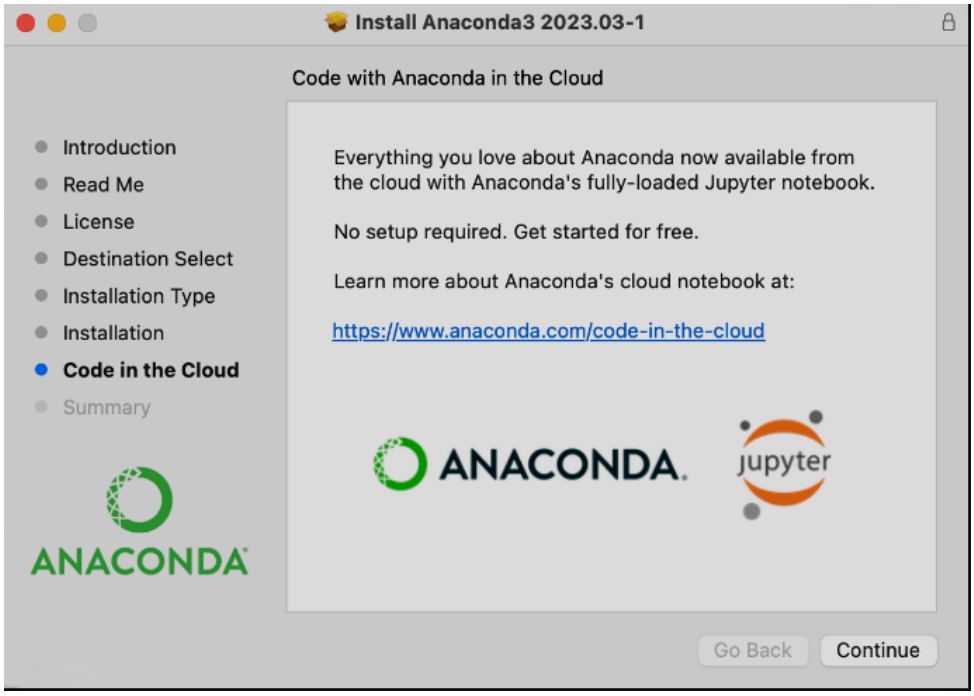
7. Optional: To learn more about Anaconda's cloud notebook service, go to https://www.anaconda.com/code-in-the-cloud. Or click Continue to proceed.



8. A successful installation displays the following screen:

9. Verify your installation.

10. Close terminal and re-open 'Terminal' if you opened it. You will observed '(base)' appearing before the prompt in terminal. It means that the conda environment is setup in your shell. If (base) does not appear but 'conda' command is working, you can type the following based on the shell you used (bash, zsh, fish). The following is for 'bash'. You need to replace it with the shell you are using.

```
User-Macbook: conda init bash
```

11. Create a conda environment by running the command: (assume your conda environment is named as 'mlaenv'. You may name it as whatever name you like such as mlaenv or SAPython with certain python version 3.x (>3.8))

```
(base) User-Macbook: conda create -n mlaenv python=3.9
```

12. After creating the environment, activate it by running the command:

```
(base) User-Macbook: conda activate mlaenv
```

# Set up Machine Learning Environment for Python

a) Ensure you have activated your Anaconda environment.

b) Install the essential machine learning packages into your Anaconda environment. Run the following command. At this stage, you might have already installed some of the packages.

```
(mlaenv) User-Macbook: conda install jupyter numpy
pandas matplotlib seaborn scikit-learn python-graphviz
```

c) Examine the path of the packages installed.

```
(mlaenv) User-Macbook: conda env list
```

d) The package **graphviz** is used for Decision Tree workshop. Note that graphiviz directory is installed in the subdirectory of the environment directory. You need to import files from graphviz in python files.

## Appendix – Some Anaconda Command

Check the version of Anaconda

```
conda list anaconda
```

List all packages installed in the environment

```
conda list
```

Activate the environment

```
conda activate *your_env
```

Determine your environment

```
conda env list
```

View a list of packages in your environment

```
conda list
```

Launch jupyter notebook [In this course, you may choose to use other IDE such as VS Code]

```
jupyter notebook
```

Create a kernel for jupyter notebook linked with the conda environment using ipykernel

```
python -m  ipykernel install --user --name *your_env --display-
```

© NUS. All rights reserved.

```
name "*your_env "
```

Deactivate the environment

```
conda deactivate
```
